1.1 ROD SEALS AND WIPERS

Surface quality
The roughness values stated in table 1.1 must be observed in both the R_a and R_t areas.

Open or closed grooves
Table 1.2 can be used to establish whether a seal can be fitted in closed grooves (1). In the case of a specific cross-section B, we recommend fitting in open grooves (2) if the diameter of the rod is less than the minimum diameter (d_{min}).

Chamfers
Table 1.3 lists the chamfer lengths K to be observed.

Roundings
Sharp edges must be avoided. Table 1.4 lists the radii to be observed.

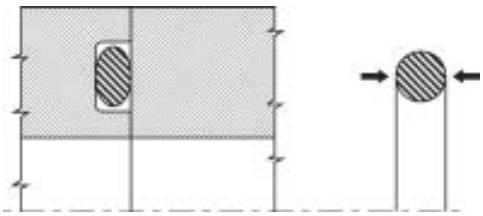
1.4 STATIC SEALS – AXIAL INSTALLATION

The static seal is squeezed between its two side faces.



2. CORRECT INSTALLATION

Hydraulic seals can be damaged if they are not correctly installed. This can result in many problems, which can be avoided by observing the following guidelines:

- Check that the groove diameters, tolerances, surface qualities and chamfers are based on the values given in this catalogue.
- Ensure that the seal does not come in contact with sharp edges, bored holes or threads during assembly.
- All metal parts must be absolutely clean and free of swarf, weld splatter and defects.
- All seals must be lubricated before assembly with the same liquid or a liquid compatible with that which will be used in the hydraulic system.
- Do not use sharp-edged tools for installation. Do not allow seals to be deformed for a prolonged period during installation.
- Ensure the seal is correctly oriented with respect to the direction of fluid pressure. The same applies to all the other parts.

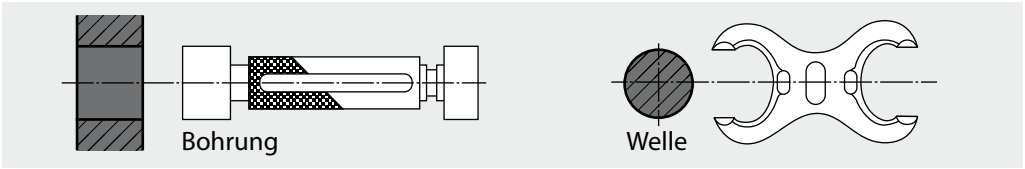
5. TOLERANCES AND FITS

Table of ISO tolerances basic hole / basic shaft in accordance with **ISO 286**.
The allowances for shafts are given in accordance with **DIN 7160**; for holes the standard is **DIN 7161**.

T

ALLOWANCES FOR HOLES AND SHAFTS



The ISO system for tolerances and fits relate to all linear parameters such as external dimensions, internal dimensions, diameters, lengths, widths, heights and thicknesses.

A reference temperature 20 °C applies to all the dimensions defined in this system. Tables 5.1, 5.2 and 5.3 contain a selection of tolerances that are used successfully in the field of tool and mould making, and are the preferred values in HASCO standards. These tolerances are used in our technical documents to precisely describe our products. These tolerances can also be used to advantage in other areas.

8. BUSHES

8.1 GENERAL

T

Technical data

To make things clearer, we would like to define in advance some important technical data used repeatedly in this document. For this purpose, we shall consider a bush with an internal diameter "d" and a width "L".

Specific bearing load = p (N/mm²)

For a vertically applied load "F" (N):

$$p = \frac{F}{d \cdot L}$$

Sliding speed = v (m/s)

In the case of rotation: for a rotation speed "n" (min^{-1}):

$$v = \frac{d \cdot \pi \cdot n}{60 \cdot 10^3}$$

In the case of oscillatory motion: where "n" is the frequency of the oscillatory motion (min^{-1}) and "μ" is the amplitude of the motion expressed in degrees:

$$v = \frac{d \cdot \pi}{60 \cdot 10^3} \cdot \frac{2\mu \cdot n}{360}$$

pv value = p x v (N/mm² x m/s)

Calculation of the service life

The service life of a bush depends on the specific bearing load, sliding speed, operating temperature and the shaft material (surface quality and hardness). On request, we can calculate a service life for you, but this can be no more than a guide.

Installing the bushes

Use the basic arrangement shown in Figure 8.1 to install bushes with an external diameter of up to 50 mm. By machining the bearing surface at a specific height h, the bush can be pressed an exact depth h into the hole.

Use an auxiliary ring as shown in Figure 8.2 to fit bushes with an external diameter greater than 50 mm. On request, we can calculate the press-in force FE for you.

Installation principle

We recommend protecting the bushes against dirt by using type SWP seal ends or shaft seal rings (Fig. 8.3). Finally, chamfers should preferably be machined in order to prevent stress concentrations at the edges of the bushes (Fig. 8.4), or the bushes should project above the surrounding material (Fig. 8.5).

The BK090 bush has many advantages:

- Maintenance-free operation
- Relubricatable
- Suitable for dirty conditions
- Shock and vibration resistant
- High permissible load

Areas of application

BK090 bushes are suitable for rotary and oscillatory motions. Initial lubrication with grease is advisable, and continual lubrication substantially lengthens the service life of the slide bearing.

Application examples:

- Attachment eyes for hydraulic cylinders
- Forestry machinery
- Agricultural equipment
- Conveyors and elevators
- Construction machinery, ...

9. O-RINGS

9.1 DESCRIPTION OF O-RINGS

O-rings are ring-shaped seals with a round cross-section (a torus) defined by the inside diameter (D) and the cross-sectional diameter (d). It is the most common seal type for hydraulic and pneumatic applications.

O-rings have the following advantages:

- The groove is simple and easy to machine
- Large choice of compounds: NBR, FPM, EPDM, silicone, PTFE, PUR, ...
- Easy to install due to its symmetry
- Attractive price thanks to new production techniques
- Extremely wide variety of applications: static, dynamic (both linear and rotary), ...
- Compact design

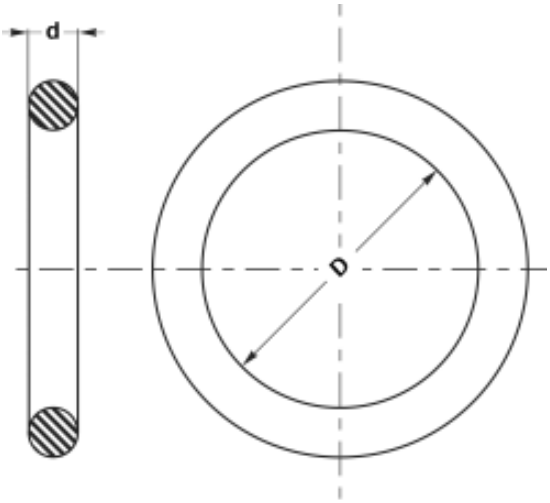

Figure 9.1:

9.2 PRINCIPLE OF O-RINGS

The functional principle is summarised in Figure 9.2:

- The O-ring is installed in a groove with a depth g smaller than the diameter d of the cross-section (Fig. 9.2).
- After installation, the O-ring seal is squeezed andthis creates a pressing action (Fig. 9.3).
- The media exerts pressure on the O-ring and intensifies the initial pressing action (Fig. 9.4).

The initial precompression (Fig. 9.3) is very important! Depending on the application and material, the compression of the elastomer will change as follows:

- From 3 to 20 % dynamic seal (pneumatic and hydraulic). In this catalogue, the initial pressure fluctuates between 12 and 14 % for a dynamic seal
- From 15 to 30 % static seal. In this catalogue, the initial pressure used for a static seal fluctuates between 17 and 27 %.

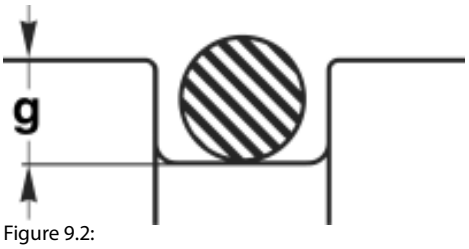

Figure 9.2:

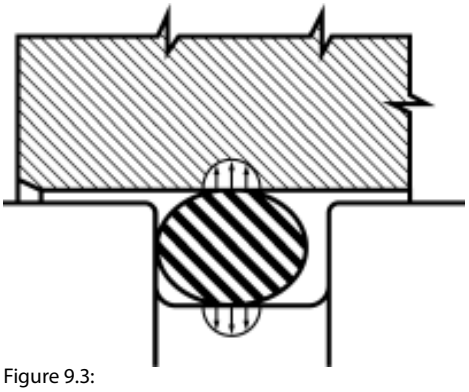

Figure 9.3:

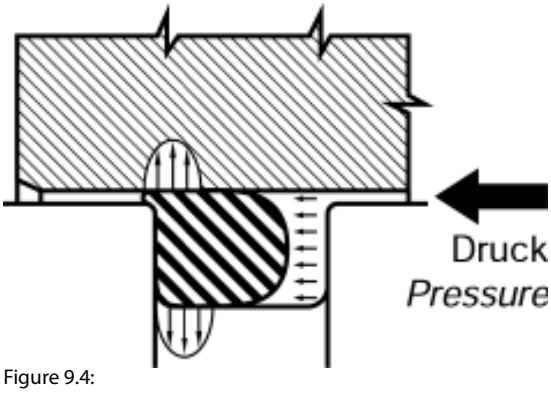

Figure 9.4:

9.3 TECHNICAL FEATURES OF O-RINGS

Static working pressure
- up to 150 bar for NBR 70 shore A without back-up ring
- up to 500 bar for NBR 70 shore A with back-up ring

Linear speed
Up to 0.5 m/s

Speed with rotational movements
Up to 2 m/s

C.S.: compression set
Compression set is a very important property because it expresses the time-related elasticity of the elastomer used.

Figures 9.5, 9.6 and 9.7 show an O-ring with cross-sectional diameter (d) compressed with a force (F) resulting in a value (C) for a specified time and temperature.

The value R is measured after the specified time has elapsed:

$$\text{C. S. (\%)} = \frac{d - R}{d - C} \cdot 100$$

A completely elastic material has a C.S. of 0 %, while a completely inelastic material has a C.S. of 100 %.

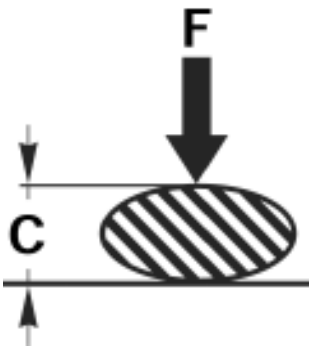

Figure 9.6:

Figure 9.7:

9.4 PERMISSIBLE CLEARANCE GAP OF O-RINGS

The highest permissible clearance gap **e** can be determined from the chart in Figure 9.8. The clearance gap must be less than the value shown left of the relevant curve and depends on the pressure used.

9.5 DIMENSIONAL TOLERANCES FOR O-RINGS IN ACCORDANCE WITH ISO 3601-1:2008 CLASS B

The tolerances for the cord diameters d_2 are shown in Table 9.9.
The tolerances for the internal diameter d_1 are calculated **in accordance with ISO 3601-1:2008, Class B** using the following formula:

$$d_1 = (d_1^{0.95} \cdot 0.009) + 0.11 \text{ [mm]}$$

This formula is for use only with metric dimensions. The tolerances for internal diameters d_1 up to 600 mm are listed in Table 9.10.

9.9 INSTALLATION INSTRUCTIONS FOR O-RINGS

Installation and clearance gap

We give advice on the tolerances H7 / f6 for installation. The highest permissible clearance gap **e** can be determined from the chart in Figure 9.8 and 9.4 "Permissible clearance gap of O-rings". The clearance gap **e** must be less than the value read from axis to the left of the relevant curve and depends on the pressure used.

Surface quality

The roughness values stated in table 9.15 must be observed in both the R_a and R_t areas.

Chamfers

Table 9.14 lists the chamfer lengths K to be observed.

Roundings

Sharp edges must be avoided. The radii to be observed are shown on the following pages.

10. BACK-UP RINGS

10.1 EXTRUSION

Extrusion problems occur when **the clearance gap e** between the parts in relation to the pressure deforming the O-ring is too large. The O-ring becomes gradually worn at the edges and wears out completely over time (Fig. 10.1).

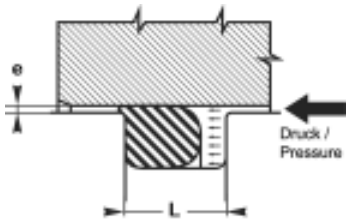

Figure 10.1:

The groove is widened by the value **E (thickness of the back-up ring)**. This back-up ring is installed on the side facing the direction of pressure. This supports the O-ring and solves extrusion problems (Fig. 10.2).
Back-up rings are used similarly for double-acting sealing systems. In this case, two back-up rings are required (Fig. 10.3).

10.2 PROFILES AND MATERIALS

We recommend solid back-up rings for internal and external grooves. PTFE must be used in applications with high temperatures and special fluids. For external grooves, the back-up rings have to be cut through to allow installation.

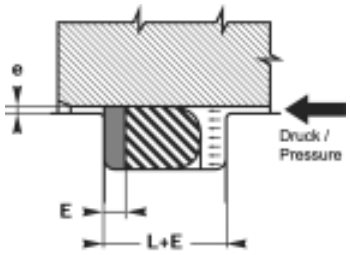

Figure 10.2:

10.3 FURTHER INFORMATION

Although a back-up ring is a very simple product, its choice and dimensions can be very complex, as we will demonstrate below.

A The problem of **replacing existing parts**: there is an enormous difference in the depth of the grooves used. The initial compression can vary between 10 and 30 % (see page 228).

Example: our standard rings BU and PBK. For an O-ring d = 2.62 mm, the section of the ring will be 2.25 mm for the PBK and 2.18 mm for the BU. Therefore the determination of the dimensions of the existing pieces must be done very carefully, because any dimension is possible; **every manufacturer uses different standards**.

Incorrectly determined dimensions can have disastrous consequences. If the ring is a poor fit for the groove, it can cause the following problems:

- If the cross-section of the ring is too large, installation will be difficult, if not impossible and the ring will inevitably wear out (see Fig. 10.4).
- On the other hand, if the cross-section is too small, there is no point in installing it: the extrusion problem is as bad as ever, as can be seen in Figure 10.5.

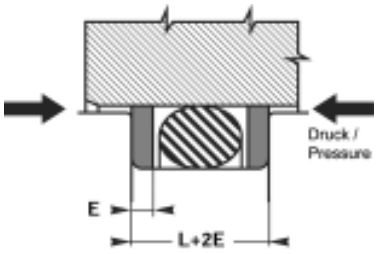

Figure 10.3:

B With respect to the **new versions**, the seal manufacturers' standard ranges are very often limited. The same ring is used for static and dynamic sealing.

Example: our PBK rings are often used for static sealing. However, they are more suitable for dynamic applications (see Table 9.13 in "9.8 Dynamic seal for hydraulic cylinders"). PBK rings are used in static applications mainly on the grounds of economy. However this conflicts with the groove depth we recommend in "9.9 Installation instructions for O-rings". For dimensions corresponding to those in Table 9.14, we recommend a DST 108 in H-PU.

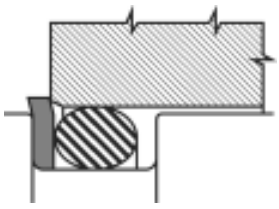

Figure 10.4:

Selecting a back-up ring for a new design is completely different to selecting one as a replacement.

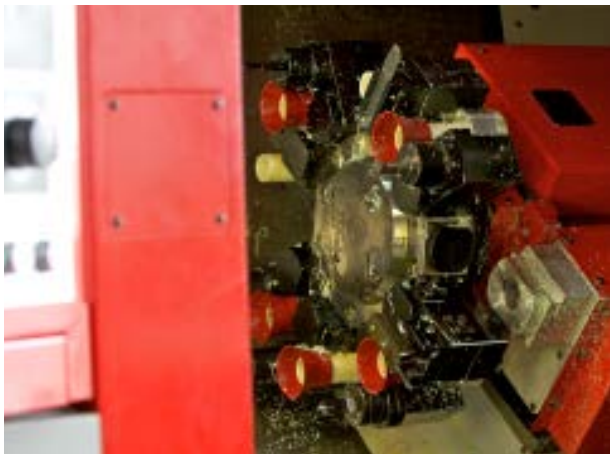
12 ON-DEMAND SEAL PRODUCTION



The HANSA-FLEX seal production centre
With two SEAL-MASTER CNC manufacturing facilities we are able to produce precision seals and special turned parts immediately in plastic or aluminium from 5 – 520 mm using computer-assisted manufacturing techniques. We store thousands of seals as datasets in the production centre's computer ready for just-in-time manufacture of seals from 5 – 520 mm directly to order. We offer same-day supply of almost any seal, whether standard or special profile.

The advantages of seal production
All seals and special turned parts can be produced as custom parts or standard parts in a mass series or individually with the highest level of precision. Our production software has over one hundred pre-programmed standard profiles. Hence, we are capable of adapting to the specific needs of our customers.

Furthermore, we maintain a standard seal stock with over 11,000 different seal types and dimensions ready and waiting for our customers.

MK

Measuring cone for O-rings

With the measuring cone set MKS5-284, all popular O rings within the diameter range of 5 - 285 mm can be measured. In order to comply with the demands made on a measuring device an especially tough high-quality material was used for its manufacture. The measuring cone set is comprised of seven individual segments which can be inserted into each other for storing or transportation. When set up, a measuring tower of maximum 1.64 m is formed.

Design: Measuring cone for O-rings

Identification	Measuring range
MKS 5-284	5 - 284 mm
MK 5-44	5 - 44 mm

UNI-MESSSCHIEBER

Universal Vernier callipers

For an exact description of seals, information is generally required on the metallic installation space. The required measuring instruments are normally only suitable for one application. This vernier caliper gauge, on the other hand, can be universally used for measurements on seal housings, pistons and rods. It can determine the exact depth and width of inside and outside grooves. It is thus an ideal measuring tool for repair and maintenance workshops.

Design: Monitor with three display possibilities
Measurable dimensions: Inside and outside diameter, groove depth, groove width

Identification	Measuring range	Inside measurement	Groove width inside	Groove depth inside
UNI-MESSSCHIEBER	0 - 200 mm / 0 - 8"	above 20 mm	above 3 mm	up to 20 mm / 3/4"
